

I'm really sorry to see none of Clive's suggestions for non-linearly weighted voting allocations. This removes the need for an arbitrary cap, instead automatically tailing off the rate of increase of influence as domain count grows. My personal preference is for votes =  $\log_2(2n)$ , where n is the number of domains registered.

But that's not on offer in the consultation paper. Of those on offer, I find (3) to be the compromise which best addresses the concerns already raised by so many on the mailing list.
